

# The Geometric Model of similarity

- One view of similarity is that it is analogous to **proximity** in some **mental space**
  - i.e. **dissimilarity**  $\leftrightarrow$  **distance**
- That is, mental representation of the perceptual features takes the form of a **mental space** analogous to a physical space
- **Multidimensional Scaling (MDS)** is a statistical technique for visualizing this space
- Given a set of items and judgments of dissimilarity among the items, MDS finds positions in an imaginary space such that inter-item distances match judged dissimilarity as closely as possible
- Starting in about 1957, psychologists have plotted MDS spaces for thousands of types of items

# Multidimensional scaling (MDS)

MDS solution:

- Subjects are asked to rate the similarity of pairs of objects
- **Multidimensional Scaling** (MDS) is used to reconstruct the corresponding distances in the mental space

# Mechanics of MDS

Subjective similarity ratings:

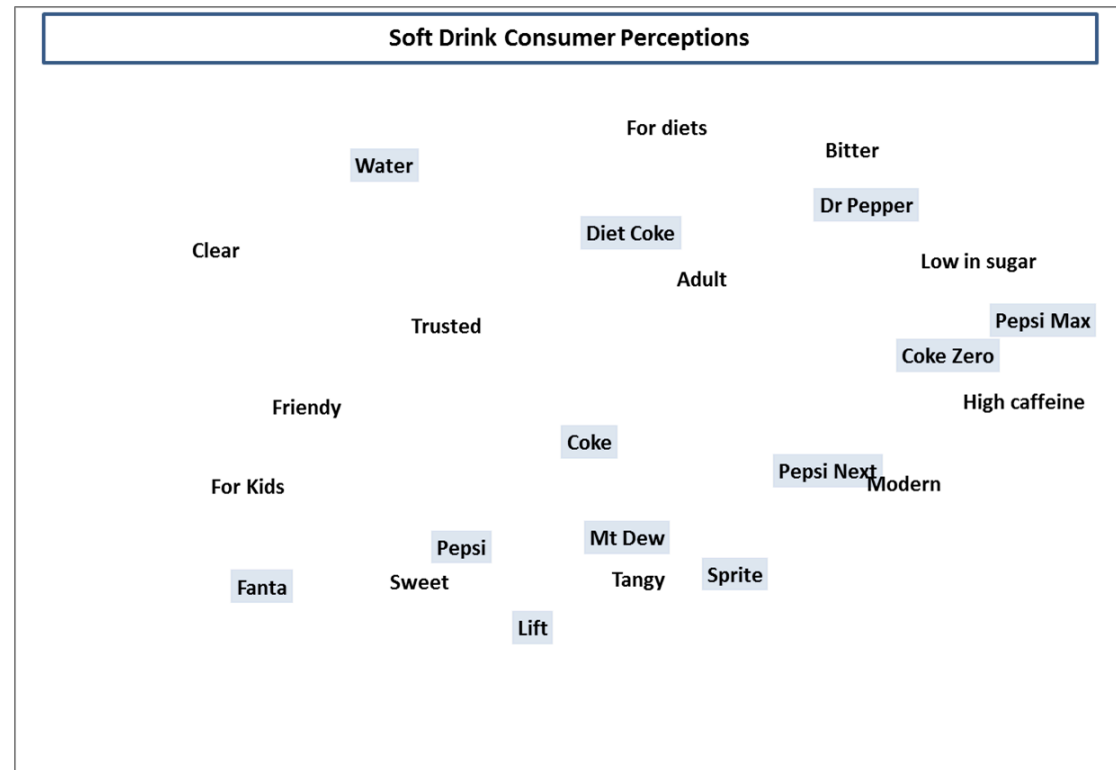

tiger	lion	?
tiger	wolf	?
lion	wolf	?
tiger	deer	?
lion	cow	?
wolf	deer	?
lion	deer	?

deer  
cow  
wolf  
tiger  
lion  
2D solution

# Questioning the geometric model

- But about 1980, Tversky & Kahneman questioned whether mental dissimilarity actually obeys the mathematical laws of distance

- These laws include the **metric axioms** or **distance axioms**, including:

- **Symmetry**:  $d(a,b) = d(b,a)$

- **Triangle inequality**:  $d(a,b) + d(b,c) \geq d(a,c)$

i.e.: “the shortest distance between two points is a straight line”

# There is more than one way to measure distance

Euclidean distance (“as the crow flies”) =  $\sqrt{(x_1 - x_2)^2 + (y_1 - y_2)^2}$

Both  
metrics  
obey the  
**distance  
axioms**

City-block distance =  $|x_1 - x_2| + |y_1 - y_2|$

General formula (Minkowski):  $D = \left( \sum (\Delta F)^r \right)^{1/r}$   
 $r = 1 \rightarrow$  city-block  $r = 2 \rightarrow$  Euclidean

# Tversky & Kahneman: Does **similarity** obey the distance axioms?

- Symmetry: **No**.
  - “An apple is similar to a pomegranate” (less preferred) vs
  - “A pomegranate is similar to an apple” (more preferred)
- Triangle inequality: **No**.
  - Jamaica is similar to Cuba; (very similar)
  - Cuba is similar to North Korea (very similar)
  - Is Jamaica similar to North Korea? (very dissimilar)

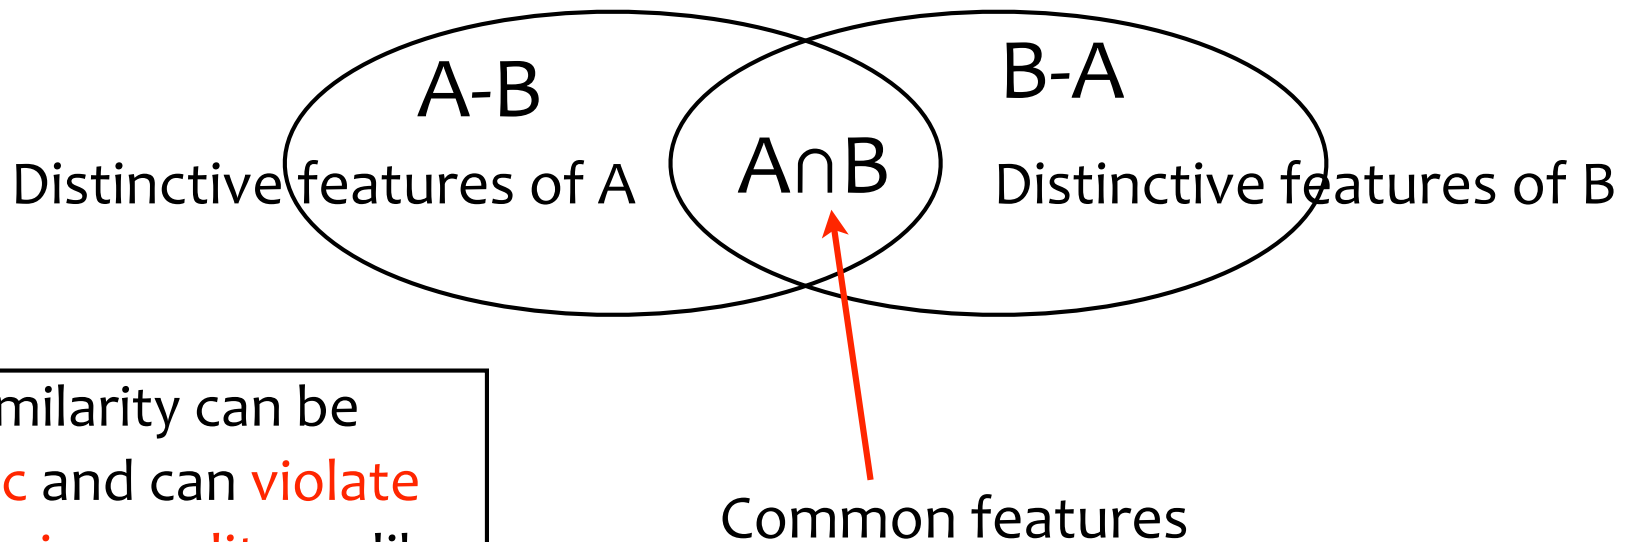

# Featural models of similarity

**Features** here are discrete attributes of objects

Kahneman & Tversky's "Contrast model" of similarity:

$$\text{sim}(A,B) = w_1 f(A \cap B) - w_2 f(A - B) - w_3 f(B - A)$$

Featural similarity can be asymmetric and can violate the triangle inequality — like human similarity judgments
